Do you need a diff drop kit?

A disadvantage of Independent Front Suspension (IFS) is the increased strain on the CV axles when lifting the vehicle over 2.5 inches. At higher lifts, the CV axles often operate at a steep angle, which can put constant stress on the joints and lead to premature wear.

To address this, a differential drop kit is commonly used. As the name suggests, this kit lowers the differential by approximately 1 inch. By dropping the differential, the angle of the CV axles is reduced, which helps alleviate strain and minimize the risk of premature axle joint wear.
